LARGE-SCALE BUSINESS GAMES FOR ASSURANCE OF LEARNING PURPOSES

Joseph Wolfe

Jwolfe8125@aol.com

ABSTRACT

It has been implied and asserted that business games can play a major role in meeting the AACSB’s Assurance of Learning directives. This study analyzed the online playing behaviors of 836 undergraduate students on 182 teams in twenty six industries playing a very complex game. The top-tier firms exhibited higher degrees of problem-solving Variety, Depth and Endurance, higher levels of within-group business function information gathering than each industry’s bottom-tier companies. The top-performing companies were also more externally-related based on the proportions of information sought. It was concluded a large-scale game requires of its successful players, group problem-solving and decision-making skills the AACSB believes are needed for today’s well-educated business student.

INTRODUCTION

In 1991 the AACSB took the concepts of the total quality movement that were being taught in its accredited schools and made them part of its mission-based accreditation procedures. Under these new “outcomes assessment” guidelines schools were allowed great flexibility in determining whether their programs were meeting the goals of their mission statements. Schools typically used indirect accomplishment measures in the form of conveniently-gathered student, alumni and employer feedback. Two years later, based on the lack of the creation of true, direct measures of learning, the AACSB called for the use of internally-derived measures of coursework and program success. Most schools responded to this requirement through the use of instruments such as course grades, teacher evaluations, graduation rates and other instructor-controlled methods.

Because of halo effects, subjectivity and the lack of comparability between programs and institutions associated with these types of instruments, the AACSB strengthened its guidelines. These were done under its Assurance of Learning (AoL) initiative (AACSB, 2007). These guidelines suggested the use of objective, standardized tests, and rigorous, twice-reviewed analyses of student work for both individually and jointly prepared cases and class exercises and projects. It has subsequently gone even further, in its popular publications (Bisoux, 2008) and in its most-recent guidelines regarding games and active learning methods. As stated in its Eligibility Procedures and Accreditation Standards for Business Accreditation (2011, 57),

The most effective learning takes place when students are involved in their educational experiences. Passive learning is ineffective and of short duration. Faculty members should develop techniques and styles that engage students and make students responsible for meeting learning goals. Many pedagogical approaches are suitable for challenging students in this way– problem-based learning, projects, simulations, etc.

This paper investigates the degree a large-scale business game rewards those players and teams that engage in the problem-solving and group decision-making skills that now-must be measured according to the AACSB’s action-oriented accreditation standards. It is important to investigate whether games can be used in this fashion. This is not only because of the AACSB’s endorsement of them for such a purpose, but also because the field’s most-popular games supply adopters with examinations that can be used in such a fashion (The Business Strategy Game, n.d.; CAPSTONE, n.d.; Marketplace Live, n.d.). In investigating this matter the paper took an action-oriented perspective by examining the online decision-making behaviors exhibited by those playing a business game. It was reasoned that such a game could be used for assurance of learning purposes if economic success in the game was associated with the higher use of the problem-solving and group decision-making skills the AACSB believes must be practiced in the schools it accredits.

LITERATURE REVIEW

Since their inception in the late-1950s, business games have been recognized as being problem-solving exercises (Anderson & Lawton, 2004). Depending on the game’s scope, depth and detail, a good business game embraces all the structural elements of a good, teachable problem. As elaborated by Lohman (2002), the exact nature, or even the existence of a problem, should not be clear. The information needed to solve the problem may not exist, or may be not easily captured. If it has been determined there is a problem, there should be different ways to solve it with each solution having different costs, variable outcomes and different degrees of harmful side effects. Based on the amount of ambiguity and indeterminacy associated with each link in the process, there is no single perfect answer or guaranteed result. This amount of problem-solving ambiguity is greatest at the firm’s strategic apex. This ambiguity still exists at the firm’s operating core but decisions taken there have higher levels of instrumentality (Mintzberg, 1979).
Because business games are teaching and learning devices, an authoritative game possesses the types of validities required, which in turn bring about a valid learning experience (Feinstein & Cannon, 2002). Those who play these games, however, bring to the game decision-making skills and tools that may have not been completely understood, used in action-oriented applications, or applied within a larger context. This is especially true for their use in strategic management courses, the most-frequent application of these games (Faria & Nulson, 1996). It is expected that each company’s novice decision-makers will more or less use coursework theories and tools to solve the firm’s problems at both the tactical and strategic levels. Company success and profits ensue if a successful match between strategy and tactics eventually has been obtained (Wolfe & Chanin, 1993).

The cognitive and tactile skill needed to solve a Rubik cube’s riddle was chosen as a guide to the problem-solving process required of a business game player. When a business game is played much thought is involved but those thoughts are only revealed by the results of those thoughts. The game player must find a series of continuous solutions to the problems their company faces. If the game is delivered online, physical movements are required for logging on, scrolling screens and inputting decisions.

Much of the same is associated with solving the Rubik cube’s riddle. The task is to reassemble a scrambled set of six differently colored faces so that only one of those colors appears on each of the cube’s six faces. The solution entails a number of face moves, the sequential solving each of the cube’s three layers must be done without destroying any of the previously constructed layers. The player must have the patience needed to make the number of moves to reach the cube’s solution. Many do not have the patience or endurance to go through this process as the cube’s pieces can be arranged in 519 quintillion different ways. Broken down, however, the problem-solving process requires the following of the decision-maker:

1. Variety—Consider the array of cube faces shown and then proceed to make a series of moves within an overall strategy for solving the cube’s riddle.
2. Depth—Drill down or envision the arrangements of cubes below its original and evolving surfaces within the chosen strategy that will move the arrangements to a final solution.
3. Endurance—Persist in the logical turning of cube faces until the riddle has been solved.

This process, when applied to the playing of an online-delivered business game, would entail the following:

1. Variety—Viewing or visiting a wide array of different screens associated with each of the game’s functional decision-making areas.
2. Depth—Digging into the options, and alternative solutions, associated with each functionally-related decision.
3. Endurance—Staying on course until all the game’s strategic and tactical decisions have been made and submitted for processing.

### HYPOTHESES TESTED

If a business game is to be used as a tool for establishing a baseline of the knowledge being delivered by a course or degree program, it must require its players to successfully engage in the problem-solving process. In an operant conditioning sense, those decisions, and the decision-making behaviors that brought about negative results, will be punished. Those decisions, and the decision-making behaviors that brought about positive results, will be reinforced. Those behaviors that appear to have no or little effect will be extinguished (Thorndike, 1913). If a game’s players are fully engaged in the experience they should more or less begin to sense what works and what does not work. This amount of engagement, however, requires from them Variety, Depth and Endurance if they are to succeed.

This study employed three hypotheses to see if a relationship existed amongst the amount of Variety, Depth and Endurance enacted by a company was related to its economic success. The hypotheses were:

- **H₁**: High tier companies will demonstrate more Variety in their decision-making processes than low tier companies.
- **H₂**: High tier companies will demonstrate more Depth in their decision-making processes than low tier companies.
- **H₃**: High tier companies will demonstrate more Endurance in their decision-making processes than low tier companies.

### METHODOLOGY

The study’s participants (n=836) were first-year undergraduate business school students majoring in international business. They were attending a west European university. It has an enrollment of about 14,500 students per year. The university’s course assignment system randomly assigned players to teams. This resulted in mostly four and five-member firms. Twenty-six seven-

firm industries were created. Exhibit 1 indicates the eventual sizes of the teams reviewed by the end of play. Course drops occurred but they were not above the norm.

Sixty percent of the course’s grade was based on the firm’s ranked profitability within its industry. The remaining forty percent was based on the grade the team received on their completion of a strategy planning and evaluation form. Peer reviews were conducted within each team. The majority of a player’s reviews had to be an “Acceptable” to pass this part of the course’s grade requirements. During this study’s data-gathering period 99.9% of its participants received an “Acceptable” from their team mates.

The game was played intensively over a two-week period excluding an intervening weekend. Each industry ran for two and one-half years or ten simulated business quarters with all running under the same economic conditions. For this study’s purposes a firm’s success or tier assignment was indicated by its final four-quarter profits. The use of each game’s last four quarters has been found to reflect the degree to which each industry’s firms benefitted or suffered for the quality of their decisions. Using the results from these last four periods also recognizes that the rational firm would make no new strategic moves at the game’s end where there would be insufficient time to realize the benefits of such moves (Wolfe, 2013).

At the end of play each industry’s top-ranked and bottom-ranked firms were classified as those being in the game’s first or last tier based on their ranked earnings for the game’s last four periods. The problem-solving dimensions of Variety, Depth and Endurance were measured in the following fashion:

- Variety—The average number of different screens viewed/visited by players on high versus low tier companies.
- Depth—The average amount of time spent viewing/visiting each screen by players on high versus low tier companies.
- Endurance—The average amount of Variety and Depth - time, over the game’s duration, spent by players on high versus low tier companies.

RESULTS

PROBLEM-SOLVING VARIETY

Three ways were used to test the degree that companies had to be engaged in problem-solving Variety if their companies were to be successful. The first analysis looked at the absolute number of screens visited by the average company. It was reasoned, that to make an intelligent decision, the team’s players must view the types of decisions that could be made. The second Variety test dealt with the types of decisions viewed. It could be surmised that better-competing companies concentrated on those areas that were externally related and new-business related, or that the poorer performing companies focused their attention on either internal affairs, or one or two decision areas while sacrificing their attention on other

areas. The last test looked at the degree screen visits were evenly distributed within the company’s management group. Ideally all team members would participate equally in their screen visits so they would be equally prepared for their company’s decision-making process. If the company’s screen visits were highly concentrated in one or two managers, the Variety of decision-making inputs, and the power of those inputs would be restricted to the few managers.

ABSOLUTE SCREEN VISITS TEST

Exhibit 2 displays the average number of screens visited by the players on high tier vs. low tier companies during the time they managed their companies. The average high tier company visited about 70.6% more screens. The individual players on those companies visited about 51.5% more screens. These differences were significant p <=0.003.

DIFFERENT SCREEN VISITS TEST

This test was conducted based on the assumption that the more-successful companies would obtain greater Variety by viewing more-different proportions of their company’s decision-making areas. Based on the relevant management literature, they would more-often view their company’s boundary spanning screens (Burns & Stalker, 1961; March, 1991). They would do this as these screens would help them scan more features in their company’s environment (Choo, 2001; Daft, Sormunen, & Parks, 1988). The company’s decision-makers would also work more in the funds acquisition area of financial management and strategic alliance prospecting. This would have to be done in order to finance new ventures. It would also be expected that the highly successful companies would make proportionally fewer visits to their company’s “internal affairs” such as accounting, logistics and operations management and more to its marketing strategy design and channel control efforts (Mavondo, 1999).

A chi-square test of the proportions of screens viewed by each group is presented in Exhibit 3. There were significant differences between the two groups except for attention paid to viewing the game’s strategic alliances screens. These screens allowed companies to purchase or license patents, become a subcontractor or purchase or buy capacity from other firms in the industry. Accounting was not of lesser importance for the highly successful companies, as had been presumed. All other differences in proportions were as expected.
A Lorenz curve, along with its Gini Coefficient, was used to examine the amount of screen-viewing inequality or screen time concentration within companies. It has been found that participation rates fall as the decision-making group gets larger. In teaching applications the “free rider” phenomenon is well known (Latane, Williams & Harkins, 1979; Karau & Williams, 1991). It could be reasoned, however, that the more successful companies were able to elicit more within-company screen visits than was the case for the low-performing companies. This greater degree of participation, and making themselves better-prepared for any face-to-face decision-making sessions, should result in a greater range of inputs than would otherwise be the case. The average Ginis associated with each group are presented in Exhibit 4 after considering all companies with three or more players. Gini Coefficients tending towards 1.0 would indicate a high concentration of screen visits amongst very few team members. A Gini of 0.0, or one tending towards 0.0, would indicate a complete or near-equality of screen visits. Although it was previously found that the high-tier companies visited more screens, there were no differences between the groups regarding the within-team dispersion of screen visits.

### PROBLEM-SOLVING DEPTH

This study’s previous section examined the total number of different screens a company’s players viewed. It is known from that section’s results that the highest-performing companies viewed the same screens more often, but did not look at a wider Variety of them. Moreover, based on their associated Ginis, the dispersion of screen visits was equal between their members. While these are important first steps in the decision-making process, the amount of time, or Depth of each screen visit is also important. There could be many visits but each visit could be a superficial or fleeting event. Other companies could visit fewer screens but could study each one in greater detail. This section presents the amount of association found between a firm’s screen time and the company’s economic success.

### SCREEN TIME TEST

It was hypothesized that high-performing companies would spend more time on their screens than would an industry’s low-performing company. This hypothesis was accepted. As shown in Exhibit 5, after controlling for team size, the average first tier player spent about 1,373.1 total minutes on the game. This amounted to almost 24.0 hours of work. The average fourth tier player spent about one-half of that amount of time or about 12.6 hours. These differences are significant $p < 0.001$.

### DECISION-MAKING AREA SCREEN TIMES TEST

It was previously found that each success group visited a different set of screens. Exhibit 6 shows the total minutes devoted to each decision area by success group. There were no significant differences between the two success-rate groups regarding the proportions of their screen minutes devoted to the seven decision areas available. The high tier companies, however, spent a significantly larger amount of time on all their decision areas ($p < 0.002$).

### PROBLEM SOLVING ENDURANCE

A longitudinal perspective is added to the problem-
solving process when considering the decision-making group’s Endurance. In a game’s use all aspects of the organizational learning phenomenon come into play. The game’s players are assembled by some typically impersonal method, their qualities may or may not be known, and the tasks they must perform, and the skills they can mobilize, have to be learned over time in an operant conditioning fashion. Cangelosi & Dill’s (1965) pioneering work in the field of organizational learning followed the decision-making dynamics of a seven-member company in The Carnegie-Tech Management Game (Cohen, et. al., 1960). Learning was displayed as the team went through the phases of Intuition, Searching, Comprehending and Consolidating. During this process the players’ actions and discussions became less random and grew to be more focused on essentials. In a sense they became more efficient, and spent less time on the game while also becoming more successful.

This study attempted to capture this “learning” effect by (1) tracing firm and player Variety and Depth on a period-by-period basis and (2) using split-half tests of those two variables to see if there were changes overlooked when using the grand averages associated with the first two analyses.

VARIETY ENDURANCE

Exhibit 7 indicates significant differences existed between the two groups in the number of screens visited over time (p < 0.001). Both groups tracked in the same fashion with the high tier companies exhibiting a more variable path than that exhibited by the low tier companies. The peak number of visits occurred around the game’s fourth period. It was at this time the effects of the major moves were being felt. These effects were associated with expansions of American factories, building new greenfield plants or opening new markets via export sales. Once these moves had been made, it was reasonable that fewer screen visits would be needed, or that the firms had exhausted

**Exhibit 7**
Average Variety Per Decision Round
what they considered to be major endeavors with reasonable paybacks.

A split-half test was conducted to see if the emphasis, as indicated by screen visits, changed by major decision area over time. This split-half test examined every company’s first four periods vs. their last four periods. The first periods were chosen as they would be involved with the company’s Intuition and Searching phases, along with making a number of very expensive decisions. The last four periods were chosen as they entailed Cangelosi & Dill’s Consolidating phase where no major decisions would be made as there would not be enough time for any investment to make a return, and the firm would now be able to retire short-term debt, call outstanding Bonds and issue Dividends. An ANOVA indicated that when the time dimension of Endurance was added to the analysis there were overall significant differences between beginning and ending periods. The proportions of these visits are presented in Exhibit 8 which also brings out the fact that both groups changed over time regarding their attention foci (Cyert & March, 1992).

While it has been found that none of the teams shared their problem solving loads equally Exhibit 9 tracks the Gini coefficients for the number of screens visited over time. There were higher levels of concentration for the low performing companies at the beginning (p = 0.04) period and ending three periods (p = 0.006) than was the case for the high performing companies. The amount of dispersion and concentration was also more variable than that for the high performing companies. In this case there were significantly different coefficients of determination (p < 0.0001) and the low tier linear trend having lower predictive value.

**DEPTH ENDURANCE**

The previous two tests found the amount of Variety exercised by the two groups changed over time but that their trajectories found that less Variety occurred over time. Exhibit 10 displays the trends in the average amount of screen time expended by the average player over time. An ANOVA was performed on the variability of the paths shown in this exhibit. There was a significant variance in the average screen times (F = 29.71, df = 9, p < 0.0001) but both groups’ screen times fell at statistically equal rates. A test of mean between group differences in average screen times found the fourth tier companies always spent less screen time than the first tier companies (p< 0.001).

**RESULTS SUMMARY**

H1 stated that an industry’s high tier companies would demonstrate more Variety in their decision-making processes than would low tier companies. This hypothesis was supported when Variety was measured by the number and proportion of screens visited. It was not supported when Variety was measured by the average degree that company members’ visits were more equally dispersed or evenly shared within the team.

H2 stated that high tier companies would demonstrate more Depth in their decision-making processes than would low tier companies. This hypothesis was accepted through two measurements. The high tier companies spent more total minutes on their screens on a per player basis. There also was no difference in the proportions of average times spent on company decision areas.

The addition of the Endurance or time dimension to the decision-making process highlighted numerous behavioral changes. H3 hypothesized that high tier companies would...
companies would demonstrate more Endurance in their decision-making processes than low tier companies. This hypothesis was supported for both their Variety and Depth. The low performing companies also were more concentrated at their company’s beginning and ending three rounds. Overall screen times fell at the same rate for both groups but the high performers always spend more time on a quarterly basis.

**DISCUSSION**

For comparative purposes, this study used the polar opposites of success cases. This was done to put the study’s issues in sharp contrast. In reality, in any business game experience and for this application, besides there being a first-place and a seventh-place firm, there were also firms that placed at in-between ranks. Thus there could have been any number of strong second and third-place firms. Additionally, bottom-tier finishers could have been very profitable companies but just did not do as well as others. A smaller analysis was conducted on the dimensions of Variety, Depth and Endurance for firms that ranked third and fifth in their industries. This was done to see if the stark contrasts created by this study’s first vs. last analysis pertain to them.

A sample of the Variety, Depth and Endurance was conducted for second and third tier firms. That is teams whose final profits put them at their industry’s third and fifth ranks. The results of the test of problem-solving Variety are presented in Exhibit 11. It can be seen that there was a continuing decline in screen visits. These differences were significant p = 0.008 or better. Thus, there appears to be a continuum of lessening screen visits over the range of economic outcomes obtained by the game’s average company. Problem-solving Depth was measured earlier where it was found the first tier players spent about twice as much time at their screens than did the fourth tier players. Exhibit 12 indicates that the Depth levels of the typical second and third tier players resided at their industry’s middle ground. There was no significant difference between their minutes of screen time between them but the difference in their screen times between both the first tier and fourth tier companies was respectively significant at the p = 0.05 and p = 0.03 levels. Thus, the continuum associated with screen visits seems to hold true for screen times.

The last measures dealt with the Endurance levels applied to problem-solving Variety and Depth. Exhibit 13 shows the linear trends associated with the Variety of screens visited are stacked in their order of average number of screens visited. The high coefficient of determination

**Exhibit 11**
**Average Company Screen Visits by Performance Tier**
associated with the fourth tier companies was interpreted as being an indication that this group of companies was less-variable in the number of screens visited while the opposite was true for the first and third tier companies.

This study sought to determine if a large-scale, total enterprise game required its players to engage in the problem-solving process. It was found that those behaviors that indicate engagement in the decision-making process were more-often associated with high company performance. By the use of screen visits, times per visit, and the rate of decay of both of these visits, the study accessed what the players could do during their visits. As an online game the players could view, edit, save and submit their sessions. They could also print-out various forms as well as transporting them to spreadsheets. This use of screen visits and times per visit, however, does not tap the thought processes associated with those actions.

This study’s overall results should bring comfort to those who use business games. Those companies that “did the right thing”, in both strategic and tactical matters, and were dedicated enough to design and implement their strategies and tactics over the long haul, did relatively well. Direct and summary evaluations of the teaching results associated with business games, various authors have been able to state, after reading essentially the same literatures, that games do not produce (Neuhauser, 1976), do produce (Keys & Wolfe, 1990), or produce something that is not known or has not been correctly measured (Anderson & Lawton, 2009). This study, while not measuring learning, found that learning could take place, especially if the game’s players engage in the experience. Unfortunately the game also revealed the bane that has always been associated with teaching/learning situations—an unwillingness to be engaged in the learning experience, whether the experience is being facilitated via cases, lectures, movies or action projects. The measurement of problem is exacerbated even further, by gaming’s use of group decision-making teams, which allows those who wish not to be engaged can do so with little chance for detection or reprimand.

**CONCLUSION**

This study’s major data-collection device was an analysis of the online actions taken by the game’s players. There are other ways the players could have interacted with the game and their teammates, and these ways were not tapped. In examining the logs generated by the game, however, no player ever printed out their screen outputs, for possible dissemination to players who did not log on to the game. Additionally, no player ever used the game’s blogging feature to either chat or pass game-related material with each other although they could have e-mailed or text messaged their partners.

Further research should also be conducted using other large-scale games. Games simpler than the one used in this study could be just as useful for assurance of learning purposes, while being less-burdensome on its adopters and players. Further research should also be conducted using other measures of player engagement in the learning process. User diaries, extended debriefings and recorded sessions have been used in past studies although all are subject to either the Hawthorne Effect or after-the-fact rationalizations.

The AACSB (2010) proposes that “students achieve knowledge and skills for successful performance in a complex environment requiring intellectual ability to organize work, make and communicate sound decisions, and react successfully to unanticipated events.” In its publications it has provided or referenced testimonial-type evidence of the efficacy of computer-based games in
Assurance of Learning initiatives (Bisoux, 2008; Martell & Calderon, 2005). Because a game of the type used here appears to have created an appropriate decision-making environment to assess whether some of the AACSB’s proposals have been achieved, the next step would be to tie each team’s actual decisions to the school’s Mission Statement. The AACSB itself recommends that instructors have input into the types and levels of questions posed in any internally-derived instrument and therefore any game-related questions should test whether the student recognizes and correctly applies theory and tools supposedly taught.

To this end, the publishers and authors of the field’s three major larger-scale games, have recognized their games’ potential and have created instruments they suggest can be used for assurance of learning purposes (CAPSTONE, n.d.; Marketplace Live, n.d.; The business strategy game, n.d.). A brief review of the questions posed by their instruments, however, reveals their questions pertain to game specifics rather than the theory and tools the players should have had to employ to both answer the question and successfully play the game. This observation assigns even greater credibility to the AACSB’s recommendation that the instructors should have input into the questions that supposedly detect whether learning has occurred. The questions that are posed should be theory-driven, tool-kit oriented and problem-solving in nature. Moreover they should be supportive of the school’s AACSB submitted mission statement (AACSB, 2011) rather than serving as indications that the players were technically engaged in the simulation itself as a product or teaching technology. Those that have created game test instruments should engage in research that objectively shows that a strong link exists between the business game firm’s results and the correct use of the course’s theories and tools as applied to the game’s problem-solving situation. When such links have been established the promises of business gaming’s earliest years will be realized and that a new use has been found for them as assessment devices.
